Presented by Yifan Ge

# Section 1

## Background

# Derivative-Free Optimization

- $\operatorname{argmin}_{x \in X} f(x)$
- ~~linearity, convexity,~~ **differentiability**
- genetic algorithms, randomized local search, estimation of distribution algorithms, cross-entropy methods, Bayesian optimization methods, optimistic optimization methods, etc.
- usually model-based

# Classification-based Optimization

---

**Algorithm 1** classification-based optimization
 

---

**Input:**

$f$ : Objective function to be minimized;  
 $\mathcal{C}$ : A binary classification algorithm;  
 $\lambda \in [0, 1]$ : Balancing parameter;  
 $\alpha_1 > \dots > \alpha_T$ : Threshold for labeling;  
 $T \in \mathbb{N}^+$ : Number of iterations;  
 $m \in \mathbb{N}^+$ : Sample size in each iteration;  
 Sampling: Sampling sub-procedure.

**Procedure:**

- 1: Collect  $S_0 = \{x_1, \dots, x_m\}$  by i.i.d. sampling from  $\mathcal{U}_X$
- 2: Let  $\tilde{x} = \operatorname{argmin}_{x \in S_0} f(x)$
- 3: **for**  $t = 1$  to  $T$  **do**
- 4:   Construct  $B_t = \{(x_1, y_1), \dots, (x_m, y_m)\}$ ,  
    where  $x_i \in S_{t-1}$  and  $y_i = \operatorname{sign}[\alpha_t - f(x_i)]$
- 5:   Let  $S_t = \emptyset$
- 6:   **for**  $i = 1$  to  $m$  **do**
- 7:      $h_t = \mathcal{C}(B_t)$ , where  $h_t \in \mathcal{H}$
- 8:      $x_i = \operatorname{Sampling}(h_t, \lambda)$ , and let  $S_t = S_t \cup \{x_i\}$
- 9:   **end for**
- 10:    $\tilde{x} = \operatorname{argmin}_{x \in S_t \cup \{\tilde{x}\}} f(x)$
- 11: **end for**
- 12: **return**  $\tilde{x}$  and  $f(\tilde{x})$

---

- Let  $\operatorname{sign}[v]$  be the sign function returning 1 if  $v \geq 0$  and -1 otherwise.
- We specify the  $\operatorname{Sampling}(h, \lambda)$  as that, it samples with probability  $\lambda$  from  $\mathcal{U}_{D_h}$  (the uniform distribution over the positive region classified by  $h$ ), and with the remaining probability from  $\mathcal{U}_X$  (the uniform distribution over  $X$ ).

## Section 2

# Theoretical Study

# $(\epsilon, \delta)$ -Query Complexity

Given  $f \in \mathcal{F}$ , an algorithm  $A$ ,  $0 < \delta < 1$  and  $\epsilon > 0$ , the  $(\epsilon, \delta)$ -query complexity is the number of calls to  $f$  such that, with probability at least  $1 - \delta$ ,  $A$  finds at least one solution  $\tilde{x} \in X \subseteq \mathbb{R}^n$  satisfying

$$f(\tilde{x}) - f(x^*) \leq \epsilon,$$

where  $f(x^*) = \min_{x \in X} f(x)$ .

## Section 3

# RACOS

# Randomized Coordinate Shrinking

**Algorithm 2** The *randomized coordinate shrinking* classification algorithm for  $X = \{0, 1\}^n$  or  $[0, 1]^n$

**Input:**

- $t$ : Current iteration number;
- $B_t$ : Solution set in iteration  $t$ ;
- $X$ : Solution space ( $\{0, 1\}^n$  or  $[0, 1]^n$ );
- $I$ : Index set of coordinates;
- $M \in \mathbb{N}^+$ : Maximum number of uncertain coordinates.

**Procedure:**

- 1:  $B_t^+$  = the positive solutions in  $B_t$
- 2:  $B_t^- = B_t - B_t^+$
- 3: Randomly select  $x_+ = (x_+^{(1)}, \dots, x_+^{(n)})$  from  $B_t^+$
- 4: Let  $D_{h_t} = X, I = \{1, \dots, n\}$
- 5: **while**  $\exists x \in B_t^-$  s.t.  $h_t(x) = +1$  **do**
- 6:   **if**  $X = \{0, 1\}^n$  **then**
- 7:      $k$  = randomly selected index from the index set  $I$
- 8:      $D_{h_t} = D_{h_t} - \{x \in X \mid x^{(k)} \neq x_+^{(k)}\}, I = I - \{k\}$
- 9:   **end if**
- 10: **if**  $X = [0, 1]^n$  **then**
- 11:    $k$  = randomly selected index from the index set  $I$
- 12:    $x^-$  = randomly selected solution from  $B_t^-$
- 13:   **if**  $x_+^{(k)} \geq x_-^{(k)}$  **then**
- 14:      $r$  = uniformly sampled value in  $(x_+^{(k)}, x_-^{(k)})$
- 15:      $D_{h_t} = D_{h_t} - \{x \in X \mid x^{(k)} < r\}$

- 16:   **else**
- 17:      $r$  = uniformly sampled value in  $(x_+^{(k)}, x_-^{(k)})$
- 18:      $D_{h_t} = D_{h_t} - \{x \in X \mid x^{(k)} > r\}$
- 19:   **end if**
- 20: **end if**
- 21: **end while**
- 22: **while**  $\#I > M$  **do**
- 23:    $k$  = randomly selected index from the index set  $I$
- 24:    $D_{h_t} = D_{h_t} - \{x \in X \mid x^{(k)} \neq x_+^{(k)}\}, I = I - \{k\}$
- 25: **end while**
- 26: **return**  $h_t$

- For a subset  $D \subseteq X$ , let  $\#D = \int_{x \in X} \mathbb{I}[x \in D] dx$  (or  $\#D = \sum_{x \in X} \mathbb{I}[x \in D]$  for finite discrete domains), where  $\mathbb{I}[\cdot]$  is the indicator function.

- $D_h = \{x \in X \mid h(x) = +1\}$ .

# Classification with Ramp Loss

- Hinge Loss:  $H_s(z) = \max 0, s - z$ .
- Ramp Loss:  $R_s(z) = H_1(z) - H_s(z)$ ,  $s < 1$ .
- Objective Function:

$$f(w, b) = \frac{1}{2} \|w\|_2^2 + C \sum_l^L R_s(y_l(w^T v_l + b)).$$

- NON-CONVEX!
